```
1 Pre-submit:
2 Write a few simple test cases if sample is not enough.
3 Are time limits close? If so, generate max cases.
4 Is the memory usage fine?
5 Could anything overflow?
6 Make sure to submit the right file.
7
8 Wrong answer:
9 Print your solution! Print debug output, as well.
10 Are you clearing all data structures between test cases?
11 Can your algorithm handle the whole range of input?
12 Read the full problem statement again.
13 Do you handle all corner cases correctly?
14 Have you understood the problem correctly?
15 Any uninitialized variables?
16 Any overflows?
17 Confusing N and M, i and j, etc.?
18 Are you sure your algorithm works?
19 What special cases have you not thought of?
20 Are you sure the STL functions you use work as you think?
21 Add some assertions, maybe resubmit.
22 Create some testcases to run your algorithm on.
23 Go through the algorithm for a simple case.
24 Go through this list again.
25 Explain your algorithm to a teammate.
26 Ask the teammate to look at your code.
27 Go for a small walk, e.g. to the toilet.
28 Is your output format correct? (including whitespace)
29 Rewrite your solution from the start or let a teammate do it
30 .
31 Runtime error:
32 Have you tested all corner cases locally?
33 Any uninitialized variables?
34 Are you reading or writing outside the range of any vector?
35 Any assertions that might fail?
36 Any possible division by 0? (mod 0 for example)
37 Any possible infinite recursion?
38 Invalidated pointers or iterators?
39 Are you using too much memory?
40 Debug with resubmits (e.g. remapped signals, see Various).
41
42 Time limit exceeded:
43 Do you have any possible infinite loops?
44 What is the complexity of your algorithm?
45 Are you copying a lot of unnecessary data? (References)
46 How big is the input and output? (consider scanf)
47 Avoid vector, map. (use arrays/unordered_map)
48 What do your teammates think about your algorithm?
49
50 Memory limit exceeded:
51 What is the max amount of memory your algorithm should need?
52 Are you clearing all data structures between test cases?
```

Mathematics (2)

2.1 Equations

In general, given an equation  $Ax = b$ , the solution to a variable  $x_i$  is given by

$$x_i = \frac{\det A'_i}{\det A}$$

where  $A'_i$  is  $A$  with the  $i$ 'th column replaced by  $b$ .

2.2 Recurrences

If  $a_n = c_1a_{n-1} + \cdots + c_ka_{n-k}$ , and  $r_1, \dots, r_k$  are distinct roots of  $x^k - c_1x^{k-1} - \cdots - c_k$ , there are  $d_1, \dots, d_k$  s.t.

$$a_n = d_1r_1^n + \cdots + d_kr_k^n.$$

Non-distinct roots  $r$  become polynomial factors, e.g.  $a_n = (d_1n + d_2)r^n$ .

2.3 Trigonometry

$$(V + W) \tan(v - w)/2 = (V - W) \tan(v + w)/2$$

where  $V, W$  are lengths of sides opposite angles  $v, w$ .

$$a \cos x + b \sin x = r \cos(x - \phi)$$
$$a \sin x + b \cos x = r \sin(x + \phi)$$

where  $r = \sqrt{a^2 + b^2}, \phi = \text{atan2}(b, a)$ .

2.4 Geometry

2.4.1 Triangles

For side lengths  $a, b, c$ , and  $p = \frac{a+b+c}{2}$ ,

$$A = \sqrt{p(p-a)(p-b)(p-c)}$$

Cumradius:  $R = \frac{abc}{4A}$ , Inradius:  $r = \frac{A}{p}$

Length of median (divides triangle into two equal-area triangles):

$$m_a = \frac{1}{2}\sqrt{2b^2 + 2c^2 - a^2}$$

Length of bisector (divides angles in two):

$$s_a = \sqrt{bc \left[ 1 - \left( \frac{a}{b+c} \right)^2 \right]}$$

Law of sines:  $\frac{\sin \alpha}{a} = \frac{\sin \beta}{b} = \frac{\sin \gamma}{c} = \frac{1}{2R}$

Law of cosines:  $a^2 = b^2 + c^2 - 2bc \cos \alpha$

Law of tangents:  $\frac{a+b}{a-b} = \frac{\tan \frac{\alpha+\beta}{2}}{\tan \frac{\alpha-\beta}{2}}$

2.4.2 Quadrilaterals

With side lengths  $a, b, c, d$ , diagonals  $e, f$ , diagonals angle  $\theta$ , area  $A$  and magic flux  $F = b^2 + d^2 - a^2 - c^2$ :

$$4A = 2ef \cdot \sin \theta = F \tan \theta = \sqrt{4e^2f^2 - F^2}$$

For cyclic quadrilaterals the sum of opposite angles is  $180^\circ$ ,  $ef = ac + bd$ , and  $A = \sqrt{(p-a)(p-b)(p-c)(p-d)}$ .

2.4.3 Pick's Theorem

Polygon with integer vertices:  $A = i + \frac{b}{2} - 1$

2.5 Derivatives/Integrals

$$\frac{d}{dx} \arcsin x = \frac{1}{\sqrt{1-x^2}} \qquad \frac{d}{dx} \arccos x = -\frac{1}{\sqrt{1-x^2}}$$

$$\frac{d}{dx} \tan x = 1 + \tan^2 x \qquad \frac{d}{dx} \arctan x = \frac{1}{1+x^2}$$

$$\int \tan ax = -\frac{\ln |\cos ax|}{a} \qquad \int x \sin ax = \frac{\sin ax - ax \cos ax}{a^2}$$

$$\int e^{-x^2} = \frac{\sqrt{\pi}}{2} \text{erf}(x) \qquad \int xe^{ax} dx = \frac{e^{ax}}{a^2}(ax - 1)$$

2.6 Sums

$$\sum_{i=1}^n i^3 = \frac{n^2(n+1)^2}{4}; \sum_{i=1}^n i^4 = \frac{n(n+1)(2n+1)(3n^2+3n-1)}{30}$$

## 2.7 Series

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \dots, (-\infty < x < \infty)$$
$$\ln(1 + x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \dots, (-1 < x \leq 1)$$
$$\sqrt{1 + x} = 1 + \frac{x}{2} - \frac{x^2}{8} + \frac{2x^3}{32} - \frac{5x^4}{128} + \dots, (-1 \leq x \leq 1)$$
$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \dots, (-\infty < x < \infty)$$
$$\cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \dots, (-\infty < x < \infty)$$
$$\frac{1}{1 - x} = 1 + x + x^2 + \dots = \sum_{n \geq 0} x^n$$
$$-\ln(1 - x) = x + \frac{x^2}{2} + \frac{x^3}{3} + \dots = \sum_{n \geq 1} \frac{x^n}{n}$$
$$(1 + x)^r = \sum_{n \geq 0} \binom{r}{n} x^n$$

## 2.8 Probability theory

### 2.8.1 Discrete distributions

#### Binomial distribution

The number of successes in  $n$  independent yes/no experiments, each which yields success with probability  $p$  is  $\text{Bin}(n, p)$ ,  $n = 1, 2, \dots$ ,  $0 \leq p \leq 1$ .

$$p(k) = \binom{n}{k} p^k (1 - p)^{n - k}; \mu = np, \sigma^2 = np(1 - p)$$

$\text{Bin}(n, p)$  is approximately  $\text{Po}(np)$  for small  $p$ .

#### First success distribution

The number of trials needed to get the first success in independent yes/no experiments, each wich yields success with probability  $p$  is  $\text{Fs}(p)$ ,  $0 \leq p \leq 1$ .

$$p(k) = p(1 - p)^{k - 1}, k = 1, 2, \dots; \mu = \frac{1}{p}, \sigma^2 = \frac{1 - p}{p^2}$$

#### Poisson distribution

The number of events occurring in a fixed period of time  $t$  if these events occur with a known average rate  $\kappa$  and independently of the time since the last event is  $\text{Po}(\lambda)$ ,  $\lambda = t\kappa$ .

$$p(k) = e^{-\lambda} \frac{\lambda^k}{k!}, k = 0, 1, 2, \dots; \mu = \lambda, \sigma^2 = \lambda$$

### 2.8.2 Continuous distributions

#### Exponential distribution

The time between events in a Poisson process is  $\text{Exp}(\lambda)$ ,  $\lambda > 0$ .

$$f(x) = \begin{cases} \lambda e^{-\lambda x} & x \geq 0 \\ 0 & x < 0 \end{cases}; \mu = \frac{1}{\lambda}, \sigma^2 = \frac{1}{\lambda^2}$$

## Normal distribution

$$f(x) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

## 2.9 Markov chains

Transition matrix:  $\mathbf{P} = (p_{ij})$ , with  $p_{ij} = \Pr(X_n = i | X_{n-1} = j)$   $\pi$  is a stationary distribution if  $\pi = \pi \mathbf{P}$ . If *irreducible* (any state to any state possible):  $\pi_i = \frac{1}{\mathbb{E}(T_i)}$  where  $\mathbb{E}(T_i)$  is the expected time between two visits in state  $i$ .  $\pi_j / \pi_i$  is the expected number of visits in state  $j$  between two visits in state  $i$ . For a connected, undirected and non-bipartite graph, where the transition probability is uniform among all neighbors,  $\pi_i$  is proportional to node  $i$ 's degree. A Markov chain is *ergodic* if the asymptotic distribution is independent of the initial distribution. A finite Markov chain is ergodic iff it is irreducible and *aperiodic* (i.e., the gcd of cycle lengths is 1).  $\lim_{k \rightarrow \infty} \mathbf{P}^k = \mathbf{1}\pi$ . A Markov chain is an A-chain if the states can be partitioned into two sets  $\mathbf{A}$  and  $\mathbf{G}$ , such that all states in  $\mathbf{A}$  are absorbing ( $p_{ii} = 1$ ), and all states in  $\mathbf{G}$  leads to an absorbing state in  $\mathbf{A}$ . The probability for absorption in state  $i \in \mathbf{A}$ , when the initial state is  $j$ , is  $a_{ij} = p_{ij} + \sum_{k \in \mathbf{G}} a_{ik} p_{kj}$ . The expected time until absorption, when the initial state is  $i$ , is  $t_i = 1 + \sum_{k \in \mathbf{G}} p_{ki} t_k$ .

## 2.10 Graphs

### 2.10.1 Erdos-Gallai theorem

A simple graph with node degrees  $d_1 \geq \dots \geq d_n$  exists iff  $d_1 + \dots + d_n$  is even and for every  $k = 1 \dots n$ ,

$$\sum_{i=1}^k d_i \leq k(k-1) + \sum_{i=k+1}^n \min(d_i, k)$$

### 2.10.2 Number of Spanning Trees

Create an  $N \times N$  matrix `mat`, and for each edge  $a \rightarrow b \in G$ , do `mat[a][b]--`, `mat[b][b]++` (and `mat[b][a]--`, `mat[a][a]++` if  $G$  is undirected). Remove the  $i$ th row and column and take the determinant; this yields the number of directed spanning trees rooted at  $i$  (if  $G$  is undirected, remove any row/column).

## Data structures (3)

### FastStaticRMQ.h

**Description:** Static RMQ  $\min(V[a], V[a + 1], \dots V[b])$  in constant time.  
**Usage:** `RMQ rmq(values); rmq.query(inclusive, exclusive);`  
**Time:**  $\mathcal{O}(N + Q)$

```
1 template<typename T> struct RMQ {
2     vector<T> v;
3     int n; static const int b = 30;
4     vector<int> mask, t;
5
6     int op(int x, int y) { return v[x] < v[y] ? x : y; }
7     int msb(int x) { return __builtin_clz(1) - __builtin_clz(x); }
8     int small(int r, int sz = b) { return r - msb(mask[r] & ((1 <<
9         sz) - 1)); }
10    rmq(const vector<T>& v_) : v(v_), n(v.size()), mask(n), t(n) {
11        for (int i = 0, at = 0; i < n; mask[i++] = at |= 1) {
12            at = (at << 1) & ((1 << b) - 1);
13            while (at & op(i, i - msb(at & -at))) == i) at = at & -at;
14        }
15        for (int i = 0; i < n / b; i++) t[i] = small(b * i + b - 1);
```

```
15     for (int j = 1; (1 << j) <= n / b; j++) for (int i = 0; i + (1
16         << j) <= n / b; i++)
17         t[n / b * j + i] = op(t[n / b * (j - 1) + i], t[n / b * (j - 1) + i + (1 << (j - 1)
18         )));
19 }
20 T query(int l, int r) {
21     if (r - l + 1 <= b) return v[small(r, r - l + 1)];
22     int ans = op(small(l + b - 1), small(r));
23     int x = l / b + 1, y = r / b - 1;
24     if (x <= y) {
25         int j = msb(y - x + 1);
26         ans = op(ans, op(t[n / b * j + x], t[n / b * j + y - (1 << j) + 1]));
27     }
28     return v[ans];
29 }
```

### FenwickTree.h

**Description:** Computes partial sums  $a[0] + a[1] + \dots + a[\text{pos} - 1]$ , and updates single elements  $a[i]$ , taking the difference between the old and new value.  
**Time:** Both operations are  $\mathcal{O}(\log N)$ .

```
e62fac, 22 lines
1 struct FT {
2     vector<ll> s;
3     FT(int n) : s(n) {}
4     void update(int pos, ll dif) { // a[pos] += dif
5         for (; pos < sz(s); pos |= pos + 1) s[pos] += dif;
6     }
7     ll query(int pos) { // sum of values in [0, pos]
8         ll res = 0;
9         for (; pos > 0; pos &= pos - 1) res += s[pos - 1];
10        return res;
11    }
12    int lower_bound(ll sum) { // min pos st sum of [0, pos] >=
13        sum
14        // Returns n if no sum is >= sum, or -1 if empty sum is.
15        if (sum <= 0) return -1;
16        int pos = 0;
17        for (int pw = 1 << 25; pw; pw >>= 1) {
18            if (pos + pw <= sz(s) && s[pos + pw - 1] < sum)
19                pos += pw, sum -= s[pos - 1];
20        }
21        return pos;
22    }
23 }
```

### FenwickTree2d.h

**Description:** Computes sums  $a[i, j]$  for all  $i < I, j < J$ , and increases single elements  $a[i, j]$ . Requires that the elements to be updated are known in advance (call `fakeUpdate()` before `init()`).

**Time:**  $\mathcal{O}(\log^2 N)$ . (Use persistent segment trees for  $\mathcal{O}(\log N)$ .)

```
"FenwickTree.h"
157f07, 22 lines
1 struct FT2 {
2     vector<vi> ys; vector<FT> ft;
3     FT2(int limx) : ys(limx) {}
4     void fakeUpdate(int x, int y) {
5         for (; x < sz(ys); x |= x + 1) ys[x].push_back(y);
6     }
7     void init() {
8         for (vi& v : ys) sort(all(v)), ft.emplace_back(sz(v));
9     }
10    int ind(int x, int y) {
11        return (int) (lower_bound(all(ys[x]), y) - ys[x].begin())
12        ); }
13    void update(int x, int y, ll dif) {
14        for (; x < sz(ys); x |= x + 1)
15            ft[x].update(ind(x, y), dif);
16    }
17    ll query(int x, int y) {
18        ll sum = 0;
19        for (; x; x &= x - 1)
20            sum += ft[x - 1].query(ind(x - 1, y));
21        return sum;
22    }
23 }
```

### HashMap.h

**Description:** Hash map with mostly the same API as `unordered_map`, but ~3x faster. Uses 1.5x memory. Initial capacity must be a power of 2 (if provided).

d77092, 7 lines

```

1 #include <bits/extc++.h>
2 // To use most bits rather than just the lowest ones:
3 struct chash { // large odd number for C
4     const uint64_t C = 11(4e18 * acos(0)) | 71;
5     ll operator()(ll x) const { return __builtin_bswap64(x*C); }
6 };
7 __gnu_pbds::gp_hash_table<ll,int,chash> h({}, {}, {}, {}, {1<<16});

```

## LazySegmentTree.h

**Description:** Segment tree with ability to add or set values of large intervals and compute max of intervals. Can be changed to other things. Use with a bump allocator for better performance, and SmallPtr or implicit indices to save memory.

**Usage:** Node\* tr = new Node(v, 0, sz(v));

**Time:**  $\mathcal{O}(\log N)$ .

```

1 const int inf = 1e9;
2 struct Node {
3     Node *l = 0, *r = 0;
4     int lo, hi, mset = inf, madd = 0, val = -inf;
5     Node(int lo, int hi) : lo(lo), hi(hi) {} // Large interval of
6     inf
7     Node(vi& v, int lo, int hi) : lo(lo), hi(hi) {
8         if (lo + 1 < hi) {
9             int mid = lo + (hi - lo)/2;
10            l = new Node(v, lo, mid); r = new Node(v, mid, hi);
11            val = max(l->val, r->val);
12        }
13        else val = v[lo];
14    }
15    int query(int L, int R) {
16        if (R <= lo || hi <= L) return -inf;
17        if (L <= lo && hi <= R) return val;
18        push();
19        return max(l->query(L, R), r->query(L, R));
20    }
21    void set(int L, int R, int x) {
22        if (R <= lo || hi <= L) return;
23        if (L <= lo && hi <= R) mset = val = x, madd = 0;
24        else {
25            push(), l->set(L, R, x), r->set(L, R, x);
26            val = max(l->val, r->val);
27        }
28    }
29    void add(int L, int R, int x) {
30        if (R <= lo || hi <= L) return;
31        if (L <= lo && hi <= R) {
32            if (mset != inf) mset += x;
33            else madd += x;
34            val += x;
35        }
36        else {
37            push(), l->add(L, R, x), r->add(L, R, x);
38            val = max(l->val, r->val);
39        }
40    }
41    void push() {
42        if (!l) {
43            int mid = lo + (hi - lo)/2;
44            l = new Node(lo, mid); r = new Node(mid, hi);
45        }
46        if (mset != inf)
47            l->set(lo, hi, mset), r->set(lo, hi, mset), mset = inf;
48        else if (madd)
49            l->add(lo, hi, madd), r->add(lo, hi, madd), madd = 0;
50    }

```

## LineContainer.h

**Description:** Container where you can add lines of the form  $kx+m$ , and query maximum values at points  $x$ . Useful for dynamic programming ("convex hull trick").

**Time:**  $\mathcal{O}(\log N)$

```

1 struct Line {
2     mutable ll k, m, p;
3     bool operator<(const Line& o) const { return k < o.k; }
4     bool operator<(ll x) const { return p < x; }
5 };
6

```

```

7 struct LineContainer : multiset<Line, less<>> {
8     // (for doubles, use inf = 1/.0, div(a,b) = a/b)
9     static const ll inf = LLONG_MAX;

9 p[1] += dy*jmp;
10 cur = min(cur, make_pair(f(p), p));
11 }
12 }
13 return cur;
14 }
```

### Integrate.h

**Description:** Simple integration of a function over an interval using Simpson's rule. The error should be proportional to  $h^4$ , although in practice you will want to verify that the result is stable to desired precision when epsilon changes.

4756fc, 7 lines

```
1 template<class F>
2 double quad(double a, double b, F f, const int n = 1000) {
3 double h = (b - a) / 2 / n, v = f(a) + f(b);
4 rep(i,1,n*2)
5 v += f(a + i*h) * (i&1 ? 4 : 2);
6 return v * h / 3;
7 }
```

### IntegrateAdaptive.h

**Description:** Fast integration using an adaptive Simpson's rule.

**Usage:** double sphereVolume = quad(-1, 1, [](double x) {

return quad(-1, 1, [](double y) {

return quad(-1, 1, [](double z) {

return x\*x + y\*y + z\*z < 1; });});});

7 d S1 = S(a, c), S2 = S(c, b), T = S1 + S2;
8 if (abs(T - S) <= 15 * eps || b - a < 1e-10)
9 return T + (T - S) / 15;
```

```

10     return rec(f, a, c, eps / 2, S1) + rec(f, c, b, eps / 2, S59
11         2);
12 template<class F>
13 d quad(d a, d b, F f, d eps = 1e-8) {
14     return rec(f, a, b, eps, S(a, b));
15 }

```

## Simplex.h

**Description:** Solves a general linear maximization problem: maximize  $c^T x$  subject to  $Ax \leq b$ ,  $x \geq 0$ . Returns -inf if there is no solution, inf if there are arbitrarily good solutions, or the maximum value of  $c^T x$  otherwise. The input vector is set to an optimal  $x$  (or in the unbounded case, an arbitrary solution fulfilling the constraints). Numerical stability is not guaranteed. For better performance, define variables such that  $x = 0$  is viable.

**Usage:** vvd A = {{1,-1}, {-1,1}, {-1,-2}};

vd b = {1,1,-4}, c = {-1,-1}, x;

T val = LPSolver(A, b, c).solve(x);

**Time:**  $\mathcal{O}(NM * \#pivots)$ , where a pivot may be e.g. an edge relaxation.  $\mathcal{O}(2^n)$  in the general case.

```

1 typedef double T; // long double, Rational, double + mod<P

26    }
27    return {prod,rank};

```

## Tridiagonal.h

**Description:**  $x = \text{tridiagonal}(d, p, q, b)$  solves the equation system

$$\begin{pmatrix} b_0 \\ b_1 \\ b_2 \\ b_3 \\ \vdots \\ b_{n-1} \end{pmatrix} = \begin{pmatrix} d_0 & p_0 & 0 & 0 & \cdots & 0 \\ q_0 & d_1 & p_1 & 0 & \cdots & 0 \\ 0 & q_1 & d_2 & p_2 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & q_{n-3} & d_{n-2} & p_{n-2} \\ 0 & 0 & \cdots & 0 & q_{n-2} & d_{n-1} \end{pmatrix} \begin{pmatrix} x_0 \\ x_1 \\ x_2 \\ x_3 \\ \vdots \\ x_{n-1} \end{pmatrix}$$

This is useful for solving problems on the type

$$a_i = b_i a_{i-1} + c_i a_{i+1} + d_i, 1 \leq i \leq n,$$

where  $a_0, a_{n+1}, b_i, c_i$  and  $d_i$  are known.  $a$  can then be obtained from

$$\{a_i\} = \text{tridiagonal}(\{1, -1, -1, \dots, -1, 1\}, \{0, c_1, c_2, \dots, c_n\}, \{b_1, b_2, \dots, b_n, 0\}, \{a_0, d_1, d_2, \dots, d_n, a_{n+1}\}).$$

Fails if the solution is not unique.

If  $|d_i| > |p_i| + |q_{i-1}|$  for all  $i$ , or  $|d_i| > |p_{i-1}| + |q_i|$ , or the matrix is positive definite, the algorithm is numerically stable and neither  $\text{tr}$  nor the check for  $\text{diag}[i] == 0$  is needed.

**Time:**  $\mathcal{O}(N)$  sf9fa8, 26 lines

## 4.4 Fourier transforms

### FastFourierTransform.h

**Description:**  $\text{fft}(a)$  computes  $\hat{f}(k) = \sum_x a[x] \exp(2\pi i \cdot kx/N)$  for all  $k$ .  $N$  must be a power of 2. Useful for convolution:  $\text{conv}(a, b) = c$ , where  $c[x] = \sum a[i]b[x-i]$ . For convolution of complex numbers or more than two vectors: FFT, multiply pointwise, divide by  $n$ , reverse(start+1, end), FFT back. Rounding is safe if  $(\sum a_i^2 + \sum b_i^2) \log_2 N < 9 \cdot 10^{14}$  (in practice  $10^{16}$  higher for random inputs). Otherwise, use NTT/FFTMod.

**Time:**  $\mathcal{O}(N \log N)$  with  $N = |A| + |B|$  ( $\sim 1s$  for  $N = 2^{22}$ ) 00ced6, 35 lines

```

1 typedef complex<double> C;

```

## MillerRabin.h

**Description:** Deterministic Miller-Rabin primality test. Guaranteed to work for numbers up to  $7 \cdot 10^{18}$ ; for larger numbers, use Python and extend A randomly.

**Time:** 7 times the complexity of  $a^b \bmod c$ .

```

"ModMulLL.h"
60dcd1, 12 lines

1 bool isPrime(ull n) {
2     if (n < 2 || n % 6 % 4 != 1) return (n | 1) == 3;
3     ull A[] = {2, 325, 9375, 28178, 450775, 9780504, 179526502
4         2},
5     s = __builtin_ctzll(n-1), d = n >> s;

## 5.3 Divisibility

### euclid.h

**Description:** Finds two integers  $x$  and  $y$ , such that  $ax + by = \gcd(a, b)$ . If you just need  $\gcd$ , use the built in `_gcd` instead. If  $a$  and  $b$  are coprime, then  $x$  is the inverse of  $a \pmod{b}$ .

```

33ba8f, 5 lines

1 ll euclid(ll a, ll b, ll &x, ll &y) {
2     if (!b) return x = 1, y = 0, a;
3     ll d = euclid(b, a % b, y, x);
4     return y -= a/b * x, d;
5 }

```

## CRT.h

**Description:** Chinese Remainder Theorem.

$\text{crt}(a, m, b, n)$  computes  $x$  such that  $x \equiv a \pmod{m}$ ,  $x \equiv b \pmod{n}$ . If  $|a| < m$  and  $|b| < n$ ,  $x$  will obey  $0 \leq x < \text{lcm}(m, n)$ . Assumes  $mn < 2^{62}$ .

```

Time: log(n)
"euclid.h"
04d93a, 7 lines

1 ll crt(ll a, ll m, ll b, ll n) {
2     if (n > m) swap(a, b), swap(m, n);
3     ll x, y, g = euclid(m, n, x, y);
4     assert((a - b) % g == 0); // else no solution
5     x = (b - a) % n * x % n / g * m + a;
6     return x < 0 ? x + m*n/g : x;
7 }

```

### 5.3.1 Bézout's identity

For  $a \neq 0$ ,  $b \neq 0$ , then  $d = \gcd(a, b)$  is the smallest positive integer for which there are integer solutions to

$$ax + by = d$$

If  $(x, y)$  is one solution, then all solutions are given by

$$\left( x + \frac{kb}{\gcd(a, b)}, y - \frac{ka}{\gcd(a, b)} \right), \quad k \in \mathbb{Z}$$

## phiFunction.h

**Description:** Euler's  $\phi$  function is defined as  $\phi(n) := \#$  of positive integers  $\leq n$  that are coprime with  $n$ .  $\phi(1) = 1$ ,  $p$  prime  $\Rightarrow \phi(p^k) = (p-1)p^{k-1}$ ,  $m, n$  coprime  $\Rightarrow \phi(mn) = \phi(m)\phi(n)$ . If  $n = p_1^{k_1} p_2^{k_2} \dots p_r^{k_r}$  then  $\phi(n) = (p_1-1)p_1^{k_1-1} \dots (p_r-1)p_r^{k_r-1}$ .  $\phi(n) = n \cdot \prod_{p|n} (1-1/p)$ .  $\sum_{d|n} \phi(d) = n$ ,  $\sum_{1 \leq k \leq n, \gcd(k, n)=1} k = n\phi(n)/2$ ,  $n > 1$ . Euler's thm:  $a, n$  coprime  $\Rightarrow a^{\phi(n)} \equiv 1 \pmod{n}$ . Fermat's little thm:  $p$  prime  $\Rightarrow a^{p-1} \equiv 1 \pmod{p} \forall a$ .

7         for (int j = i; j < LIM; j += i) phi[j] -= phi[j] / i;
8 }

```

## 5.4 Fractions

### ContinuedFractions.h

**Description:** Given  $N$  and a real number  $x \geq 0$ , finds the closest rational approximation  $p/q$  with  $p, q \leq N$ . It will obey  $|p/q - x| \leq 1/qN$ .

For consecutive convergents,  $p_{k+1}q_k - q_{k+1}p_k = (-1)^k$ .  $(p_k/q_k)$  alternates between  $> x$  and  $< x$ . If  $x$  is rational,  $y$  eventually becomes  $\infty$ ; if  $x$  is the root of a degree 2 polynomial the  $a$ 's eventually become cyclic.

```

16            }
17            hi.p += lo.p * adv;
18            hi.q += lo.q * adv;
19            dir = !dir;
20            swap(lo, hi);
21            A = B; B = !adv;
22        }
23        return dir ? hi : lo;
24    }
25 }

```

## 5.5 Pythagorean Triples

The Pythagorean triples are uniquely generated by

$$a = k \cdot (m^2 - n^2), \quad b = k \cdot (2mn), \quad c = k \cdot (m^2 + n^2),$$

with  $m > n > 0$ ,  $k > 0$ ,  $m \perp n$ , and either  $m$  or  $n$  even.

## 5.6 Primes

$p = 962592769$  is such that  $2^{21} \mid p-1$ , which may be useful. For hashing use 970592641 (31-bit number), 31443539979727 (45-bit), 3006703054056749 (52-bit). There are 78498 primes less than 1 000 000.

Primitive roots exist modulo any prime power  $p^a$ , except for  $p = 2, a > 2$ , and there are  $\phi(\phi(p^a))$  many. For  $p = 2, a > 2$ , the group  $\mathbb{Z}_{2^a}^\times$  is instead isomorphic to  $\mathbb{Z}_2 \times \mathbb{Z}_{2^{a-2}}$ .

## 5.7 Estimates

$$\sum_{d|n} d = O(n \log \log n).$$

The number of divisors of  $n$  is at most around 100 for  $n < 5e4$ , 500 for  $n < 1e7$ , 2000 for  $n < 1e10$ , 200 000 for  $n < 1e19$ .

## 5.8 Mobius Function

$$\mu(n) = \begin{cases} 0 & n \text{ is not square free} \\ 1 & n \text{ has even number of prime factors} \\ -1 & n \text{ has odd number of prime factors} \end{cases}$$

Mobius Inversion:

$$g(n) = \sum_{d|n} f(d) \Leftrightarrow f(n) = \sum_{d|n} \mu(d)g(n/d)$$

Other useful formulas/forms:

$$\sum_{d|n} \mu(d) = [n = 1] \text{ (very useful)}$$

$$g(n) = \sum_{n|d} f(d) \Leftrightarrow f(n) = \sum_{n|d} \mu(d/n)g(d)$$

$$g(n) = \sum_{1 \leq m \leq n} f(\lfloor \frac{n}{m} \rfloor) \Leftrightarrow f(n) = \sum_{1 \leq m \leq n} \mu(m)g(\lfloor \frac{n}{m} \rfloor)$$

## 5.9 Lifting the Exponent

For  $n > 0$ ,  $p$  prime, and ints  $x, y$  s.t.  $p \nmid x, y$  and  $p \mid x - y$ :

- $p \neq 2$  or  $p = 2, 4 \mid x - y \implies v_p(x^n - y^n) = v_p(x - y) + v_p(n)$ .
- $p = 2, 2 \mid n \implies v_2(x^n - y^n) = v_2((x^2)^{n/2} - (y^2)^{n/2})$ .

# Combinatorial (6)

## 6.1 Permutations

IntPerm.h

**Description:** Permutation -> integer conversion. (Not order preserving.) Integer -> permutation can use a lookup table.  
**Time:**  $\mathcal{O}(n)$

```
1 int permToInt(vi& v) {
2     int use = 0, i = 0, r = 0;
3     for(int x:v) r = r * ++i + __builtin_popcount(use & -(1<<x
4         )),
5         use |= 1 << x;
6     return r;
}
```

### 6.1.1 Cycles

Let  $g_S(n)$  be the number of  $n$ -permutations whose cycle lengths all belong to the set  $S$ . Then

$$\sum_{n=0}^\infty g_S(n) \frac{x^n}{n!} = \exp\left(\sum_{n \in S} \frac{x^n}{n}\right)$$

### 6.1.2 Derangements

Permutations of a set such that none of the elements appear in their original position.

$$D(n) = (n-1)(D(n-1) + D(n-2)) = nD(n-1) + (-1)^n = \left\lfloor \frac{n!}{e} \right\rfloor$$

### 6.1.3 Burnside’s lemma

Given a group  $G$  of symmetries and a set  $X$ , the number of elements of  $X$  up to symmetry equals

$$\frac{1}{|G|} \sum_{g \in G} |X^g|,$$

where  $X^g$  are the elements fixed by  $g$  ( $g \cdot x = x$ ).

If  $f(n)$  counts “configurations” (of some sort) of length  $n$ , we can ignore rotational symmetry using  $G = \mathbb{Z}_n$  to get

$$g(n) = \frac{1}{n} \sum_{k=0}^{n-1} f(\gcd(n, k)) = \frac{1}{n} \sum_{k \mid n} f(k) \phi(n/k).$$

## 6.2 Partitions and subsets

### 6.2.1 Partition function

Number of ways of writing  $n$  as a sum of positive integers, disregarding the order of the summands.

$$p(0) = 1, \quad p(n) = \sum_{k \in \mathbb{Z} \setminus \{0\}} (-1)^{k+1} p(n - k(3k-1)/2)$$

$$p(n) \sim 0.145 \sqrt{n} \cdot \exp(2.56 \sqrt{n})$$

$n$	0	1	2	3	4	5	6	7	8	9	20	50	100
$p(n)$	1	1	2	3	5	7	11	15	22	30	627	$\sim 2e5$	$\sim 2e8$

### 6.2.2 Lucas’ Theorem

Let  $n, m$  be non-negative integers and  $p$  a prime. Write  $n = n_k p^k + \dots + n_1 p + n_0$  and  $m = m_k p^k + \dots + m_1 p + m_0$ . Then  $\binom{n}{m} \equiv \prod_{i=0}^k \binom{n_i}{m_i} \pmod{p}$ .

### 6.2.3 Binomials

multinomial.h

```
1 Description: Computes  $\binom{k_1 + \dots + k_n}{k_1, k_2, \dots, k_n} = \frac{(\sum k_i)!}{k_1! k_2! \dots k_n!}$ .
2
3 11 multinomial(vi& v) {
4     ll c = 1, m = v.empty() ? 1 : v[0];
5     rep(i, 1, sz(v)) rep(j, 0, v[i])
6         c = c * ++m / (j+1);
7     return c;
8 }
```

## 6.3 General purpose numbers

### 6.3.1 Bernoulli numbers

EGF of Bernoulli numbers is  $B(t) = \frac{t}{e^t - 1}$  (FFT-able).  
 $B[0, \dots] = [1, -\frac{1}{2}, \frac{1}{6}, 0, -\frac{1}{30}, 0, \frac{1}{42}, \dots]$

Sums of powers:

$$\sum_{i=1}^n n^m = \frac{1}{m+1} \sum_{k=0}^m \binom{m+1}{k} B_k \cdot (n+1)^{m+1-k}$$

Euler-Maclaurin formula for infinite sums:

$$\begin{aligned} \sum_{i=m}^\infty f(i) &= \int_m^\infty f(x) dx - \sum_{k=1}^\infty \frac{B_k}{k!} f^{(k-1)}(m) \\ &\approx \int_m^\infty f(x) dx + \frac{f(m)}{2} - \frac{f'(m)}{12} + \frac{f'''(m)}{720} + O(f^{(5)}(m)) \end{aligned}$$

### 6.3.2 Stirling numbers of the first kind

Number of permutations on  $n$  items with  $k$  cycles.

$$c(n, k) = c(n-1, k-1) + (n-1)c(n-1, k), \quad c(0, 0) = 1$$
$$\sum_{k=0}^n c(n, k) x^k = x(x+1) \dots (x+n-1)$$

$$c(8, k) = 8, 0, 5040, 13068, 13132, 6769, 1960, 322, 28, 1$$
$$c(n, 2) = 0, 0, 1, 3, 11, 50, 274, 1764, 13068, 109584, \dots$$

### 6.3.3 Eulerian numbers

Number of permutations  $\pi \in S_n$  in which exactly  $k$  elements are greater than the previous element.  $k$   $j$ :s s.t.  $\pi(j) > \pi(j+1)$ ,  $k+1$   $j$ :s s.t.  $\pi(j) \geq j$ ,  $k$   $j$ :s s.t.  $\pi(j) > j$ .

$$E(n, k) = (n-k)E(n-1, k-1) + (k+1)E(n-1, k)$$

$$E(n, 0) = E(n, n-1) = 1$$

$$E(n, k) = \sum_{j=0}^k (-1)^j \binom{n+1}{j} (k+1-j)^n$$

### 6.3.4 Stirling numbers of the second kind

Partitions of  $n$  distinct elements into exactly  $k$  groups.

$$S(n, k) = S(n-1, k-1) + kS(n-1, k)$$

$$S(n, 1) = S(n, n) = 1$$

$$S(n, k) = \frac{1}{k!} \sum_{j=0}^k (-1)^{k-j} \binom{k}{j} j^n$$

### 6.3.5 Bell numbers

Total number of partitions of  $n$  distinct elements.  $B(n) = 1, 1, 2, 5, 15, 52, 203, 877, 4140, 21147, \dots$ . For  $p$  prime,

$$B(p^m + n) \equiv mB(n) + B(n+1) \pmod{p}$$

### 6.3.6 Labeled unrooted trees

# on  $n$  vertices:  $n^{n-2}$   
# on  $k$  existing trees of size  $n_i$ :  $n_1 n_2 \dots n_k n^{k-2}$   
# with degrees  $d_i$ :  $(n-2)! / ((d_1-1)! \dots (d_n-1)!)$

### 6.3.7 Catalan numbers

$$C_n = \frac{1}{n+1} \binom{2n}{n} = \binom{2n}{n} - \binom{2n}{n+1} = \frac{(2n)!}{(n+1)!n!}$$

$$C_0 = 1, \quad C_{n+1} = \frac{2(2n+1)}{n+2} C_n, \quad C_{n+1} = \sum C_i C_{n-i}$$

$$C_n = 1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862, 16796, 58786, \dots$$

- sub-diagonal monotone paths in an  $n \times n$  grid.
- strings with  $n$  pairs of parenthesis, correctly nested.
- binary trees with with  $n+1$  leaves (0 or 2 children).
- ordered trees with  $n+1$  vertices.
- ways a convex polygon with  $n+2$  sides can be cut into triangles by connecting vertices with straight lines.
- permutations of  $[n]$  with no 3-term increasing subseq.

## 6.4 Young Tableaux

Let a **Young diagram** have shape  $\lambda = (\lambda_1 \geq \dots \geq \lambda_k)$ , where  $\lambda_i$  equals the number of cells in the  $i$ -th (left-justified) row from the top. A **Young tableau** of shape  $\lambda$  is a filling of the  $n = \sum \lambda_i$  cells with a permutation of  $1 \dots n$  such that each row and column is increasing.

**Hook-Length Formula:** For the cell in position  $(i, j)$ , let  $h_\lambda(i, j) = |\{(I, J) \mid i \leq I, j \leq J, (I = i \text{ or } J = j)\}|$ . The number of Young tableaux of shape  $\lambda$  is equal to  $f^\lambda = \frac{n!}{\prod h_\lambda(i, j)}$ .

**Schensted’s Algorithm:** converts a permutation  $\sigma$  of length  $n$  into a pair of Young Tableaux  $(S(\sigma), T(\sigma))$  of the same shape. When inserting  $x = \sigma_i$ ,

- Add  $x$  to the first row of  $S$  by inserting  $x$  in place of the largest  $y$  with  $x < y$ . If  $y$  doesn’t exist, push  $x$  to the end of the row, set the value of  $T$  at that position to be  $i$ , and stop.
- Add  $y$  to the second row using the same rule, keep repeating as necessary.

For  $\sigma = (5, 2, 3, 1, 4)$ ,

$$S(\sigma): \begin{array}{ccccc} & & 2 & & \\ 5 & \rightarrow & 5 & \rightarrow & 2 & 3 & \\ & & 5 & & 5 \end{array}$$

$$T(\sigma): \begin{array}{ccccc} & & 1 & & 3 & & \\ 1 & \rightarrow & 2 & \rightarrow & 2 & 3 & \\ & & 2 & & 4 & & 5 \end{array}$$

All pairs  $(S(\sigma), T(\sigma))$  of the same shape correspond to a unique  $\sigma$ , so  $n! = \sum (f^\lambda)^2$ . Also,  $S(\sigma^R) = S(\sigma)^T$ .

Let  $d_k(\sigma), a_k(\sigma)$  be the lengths of the longest subseqs which are a union of  $k$  decreasing/ascending subseqs, respectively. Then

$a_k(\sigma) = \sum_{i=1}^k \lambda_i, d_k(\sigma) = \sum_{i=1}^k \lambda_i^*$ , where  $\lambda_i^*$  is size of the  $i$ -th column.

### 6.4.1 Prufer Sequences

**Tree to seq:** Take lowest label leaf, print label of neighbour, until 2 nodes left

**Seq to tree:** deg of each node = frequency in sequence+1. take lowest 1-degree node connect it to first value in sequence, increase sequence pointer. repeat.

## 6.5 Other

### DeBruijnSeq.h

**Description:** Given alphabet  $[0, k)$  constructs a cyclic string of length  $k^n$  that contains every length  $n$  string as substr.

2dfa89, 13 lines

```
1 vi deBruijnSeq(int k, int n) {
2     if (k == 1) return {0};
3     vi seq, aux(n+1);
4     function<void(int,int)> gen = [&](int t, int p) {
5         if (t > n) { // +lyndon word of len p
6             if (n%p == 0) rep(i,1,p+1) seq.pb(aux[i]);
7             } else {

### NimProduct.h

**Description:** Product of numbers is associative, commutative, and distributive over addition (xor). Forms finite field of size  $2^{2^k}$ . Defined by  $ab = \text{mex}(\{a'b + ab' + a'b' : a' < a, b' < b\})$ . Application: Given 1D coin turning game  $G_1, G_2$   $G_1 \times G_2$  is the 2D coin turning game defined as follows. If  $x$  turning coins at  $x_1, x_2, \dots, x_m$  is legal in  $G_1$  and  $y_1, y_2, \dots, y_n$  is legal in  $G_2$ , then turning coins at all positions  $(x_i, y_j)$  is legal assuming that the coin at  $(x_m, y_n)$  goes from heads to tails. Then the Grundy function  $g(x, y)$  of  $G_1 \times G_2$  is  $g_1(x) \times g_2(y)$ .

**Time:**  $64^2$  xors per multiplication, memorize to speed up.

```

## 7.2 Matching

### DFSMatching.h

**Description:** Simple bipartite matching algorithm. Graph  $g$  should be a list of neighbors of the left partition, and  $btoa$  should be a vector full of -1's of the same size as the right partition. Returns the size of the matching.  $btoa[i]$  will be the match for vertex  $i$  on the right side, or -1 if it's not matched.

**Usage:**  $vi$  btoa(m, -1); dfsMatching(g, btoa);

**Time:**  $O(VE)$

```

## WeightedMatching.h

**Description:** Given a weighted bipartite graph, matches every node on the left with a node on the right such that no nodes are in two matchings and the sum of the edge weights is minimal. Takes  $cost[N][M]$ , where  $cost[i][j] = \text{cost for } L[i] \text{ to be matched with } R[j] \text{ and returns (min cost, match), where } L[i] \text{ is matched with } R[\text{match}[i]]$ . Negate costs for max cost. Requires  $N \leq M$ .

**Time:**  $\mathcal{O}(N^2M)$  1e0fe9, 31 lines

## 7.3 DFS algorithms

### SCC.h

**Description:** Finds strongly connected components in a directed graph. If vertices  $u, v$  belong to the same component, we can reach  $u$  from  $v$  and vice versa.

**Usage:** scc(graph, [&](vi& v) { ... }) visits all components in reverse topological order. comp[i] holds the component index of a node (a component only has edges to components with lower index). ncomps will contain the number of components.

**Time:**  $\mathcal{O}(E + V)$  76b5c9, 24 lines

```

1 vi val, comp, z, cont;
2 int Time, ncomps;
3 template<class G, class F> int dfs(int j, G& g, F& f) {
4     int low = val[j] = ++Time, x; z.push_back(j);
5     for (auto e : g[j]) if (comp[e] < 0)
6         low = min(low, val[e] ? dfs(e,g,f));
7
8     if (low == val[j]) {
9         do {
10             x = z.back(); z.pop_back();
11             comp[x] = ncomps;
12             cont.push_back(x);
13         } while (x != j);
14         f(cont); cont.clear();
15         ncomps++;
16     }
17     return val[j] = low;
18 }
19 template<class G, class F> void scc(G& g, F f) {
20     int n = sz(g);
21     val.assign(n, 0); comp.assign(n, -1);
22     Time = ncomps = 0;
23     rep(i,0,n) if (comp[i] < 0) dfs(i, g, f);
24 }

```

### BiconnectedComponents.h

**Description:** Finds all biconnected components in an undirected graph, and runs a callback for the edges in each. In a biconnected component there are at least two distinct paths between any two nodes. Note that a node can be in several components. An edge which is not in a component is a bridge, i.e., not part of any cycle.

**Usage:** int eid = 0; ed.resize(N);  
for each edge (a,b) {  
ed[a].emplace\_back(b, eid);  
ed[b].emplace\_back(a, eid++);}  
bicomps[&](const vi& edgelist) {...};

**Time:**  $\mathcal{O}(E + V)$  2965e5, 33 lines

```

1 vi num, st;
2 vector<vector<pii>> ed;
3 int Time;
4 template<class F>
5 int dfs(int at, int par, F& f) {
6     int me = num[at] = ++Time, e, y, top = me;
7     for (auto pa : ed[at]) if (pa.second != par) {
8         tie(y, e) = pa;
9         if (num[y]) {
10             top = min(top, num[y]);
11             if (num[y] < me)

```

```

        st.push_back(e);
    } else {
        int si = sz(st);
        int up = dfs(y, e, f);
        top = min(top, up);
        if (up == me) {
            st.push_back(e);
            f(vi(st.begin() + si, st.end()));
            st.resize(si);
        }
        else if (up < me) st.push_back(e);
        else /* e is a bridge */
    }
}
return top;
}
template<class F>
void bicomps(F f) {
    num.assign(sz(ed), 0);
    rep(i,0,sz(ed)) if (!num[i]) dfs(i, -1, f);
}

```

### BlockCutTree.h

**Description:** Builds the block cut tree. BCTree node  $n$  is an AP if  $n \geq cut$ , and it corresponds to node who[n][0] in original graph. Node  $v$  of the original graph is an AP if  $vmap[v] \geq cut$ .  $emap[i] = -1$  if edge  $i$  is a bridge. Otherwise,  $emap[i]$  is the BCC containing it.

**Usage:** see BiconnectedComponents.h  
edges[i] = the edge  $i$  (pair of two nodes)

**Time:**  $\mathcal{O}(E + V)$

49     }
50     return {cut, tadj, who, emap, vmap};

```

### 2sat.h

**Description:** Calculates a valid assignment to boolean variables  $a, b, c, \dots$  to a 2-SAT problem, so that an expression of the type  $(a \vee b) \wedge (a \vee c) \wedge (d \vee b) \wedge \dots$  becomes true, or reports that it is unsatisfiable. Negated variables are represented by bit-inversions ( $\sim x$ ).

**Usage:** TwoSat ts(number of boolean variables);  
ts.either(0, ~3); // Var 0 is true or var 3 is false  
ts.setValue(2); // Var 2 is true  
ts.atMostOne({0, ~1, 2}); //  $\leq 1$  of vars 0, ~1 and 2 are true  
ts.solve(); // Returns true iff it is solvable  
ts.values[0..N-1] holds the assigned values to the vars

**Time:**  $\mathcal{O}(N + E)$ , where  $N$  is the number of boolean variables, and  $E$  is the number of clauses. 5f9706, 56 lines

## MaximumIndependentSet.h

**Description:** To obtain a maximum independent set of a graph, find a max clique of the complement. If the graph is bipartite, see MinimumVertexCover.

## 7.6 Trees

### LCA.h

**Description:** Data structure for computing lowest common ancestors in a tree (with 0 as root). C should be an adjacency list of the tree, either directed or undirected.

**Time:**  $\mathcal{O}(N \log N + Q)$   
"./data-structures/RMQ.h" 0f62fb, 21 lines

```

1 struct LCA {
2     int T = 0;
3     vi time, path, ret;
4     RMQ<int> rmq;
5
6     LCA(vector<vi>& C) : time(sz(C)), rmq((dfs(C, 0, -1), ret))
7     {}
8     void dfs(vector<vi>& C, int v, int par) {
9         time[v] = T++;
10        for (int y : C[v]) if (y != par) {
11            path.push_back(v), ret.push_back(time[v]);
12            dfs(C, y, v);
13        }
14    }
15
16    int lca(int a, int b) {
17        if (a == b) return a;
18        tie(a, b) = minmax(time[a], time[b]);
19        return path[rmq.query(a, b)];
20    }
21    //dist(a,b){return depth[a] + depth[b] - 2*depth[lca(a,b)
22    ];}

```

### CompressTree.h

**Description:** Given a rooted tree and a subset S of nodes, compute the minimal subtree that contains all the nodes by adding all (at most  $|S|-1$ ) pairwise LCA's and compressing edges. Returns a list of (par, orig\_index) representing a tree rooted at 0. The root points to itself.

**Time:**  $\mathcal{O}(|S| \log |S|)$   
"LCA.h" 9775a0, 21 lines

```

1 typedef vector<pair<int, int>> vpi;

19    }
20    return ret;

```

21 }

### HLD.h

**Description:** Decomposes a tree into vertex disjoint heavy paths and light edges such that the path from any leaf to the root contains at most  $\log(n)$  light edges. Code does additive modifications and max queries, but can support commutative segtree modifications/queries on paths and subtrees. Takes as input the full adjacency list. VALS.EDGES being true means that values are stored in the edges, as opposed to the nodes. All values initialized to the segtree default. Root must be 0.

**Time:**  $\mathcal{O}((\log N)^2)$

```

1  template <bool VALS_EDGES> struct HLD {

26    friend ostream& operator<<(ostream& os, P p) {
27        return os << "(" << p.x << "," << p.y << ")"; }
28};
```

#### lineDistance.h

##### Description:

Returns the signed distance between point p and the line containing points a and b. Positive value on left side and negative on right as seen from a towards b. a==b gives nan. P is supposed to be Point<T> or Point3D<T> where T is e.g. double or long long. It uses products in intermediate steps so watch out for overflow if using int or long long. Using Point3D will always give a non-negative distance. For Point3D, call .dist on the result of the cross product.

"Point.h" f6bf6b, 4 lines

```
1 template <class P>
2 double lineDist(const P& a, const P& b, const P& p) {
3     return (double) (b-a).cross(p-a)/(b-a).dist();
4 }
```

#### SegmentDistance.h

##### Description:

Returns the shortest distance between point p and the line segment from point s to e.

**Usage:** Point<double> a, b(2,2), p(1,1);  
bool onSegment = segDist(a,b,p) <= 1e-10;

"Point.h" 5c88f4, 6 lines

```
1 typedef Point<double> P;
2 double segDist(P& s, P& e, P& p) {
3     if (s==e) return (p-s).dist();
4     auto d = (e-s).dist2(), t = min(d,max(.0, (p-s).dot(e-s)));
```

```
5     return ((p-s)*d-(e-s)*t).dist()/d;
6 }
```

#### SegmentIntersection.h

##### Description:

If a unique intersection point between the line segments going from s1 to e1 and from s2 to e2 exists then it is returned. If no intersection point exists an empty vector is returned. If infinitely many exist a vector with 2 elements is returned, containing the endpoints of the common line segment. The wrong position will be returned if P is Point<ll> and the intersection point does not have integer coordinates. Products of three coordinates are used in intermediate steps so watch out for overflow if using int or long long.

**Usage:** vector<P> inter = segInter(s1,e1,s2,e2);  
if (sz(inter)==1)

cout << "segments intersect at " << inter[0] << endl;

12    return {all(s)};
13 }
```

#### lineIntersection.h

##### Description:

If a unique intersection point of the lines going through s1,e1 and s2,e2 exists {1, point} is returned. If no intersection point exists {0, (0,0)} is returned and if infinitely many exist {-1, (0,0)} is returned. The wrong position will be returned if P is Point<ll> and the intersection point does not have integer coordinates. Products of three coordinates are used in intermediate steps so watch out for overflow if using int or ll.

**Usage:** auto res = lineInter(s1,e1,s2,e2);  
if (res.first == 1)

cout << "intersection point at " << res.second << endl;  
"Point.h" a01f81, 8 lines

```
1 template <class P>
2 pair<int, P> lineInter(P s1, P e1, P s2, P e2) {
3     auto d = (e1 - s1).cross(e2 - s2);
4     if (d == 0) // if parallel
5         return {(s1.cross(e1, s2) == 0), P(0, 0)};
6     auto p = s2.cross(e1, e2), q = s2.cross(e2, s1);
7     return {1, (s1 * p + e1 * q) / d};
8 }
```

#### sideOf.h

**Description:** Returns where p is as seen from s towards e. 1/0/-1  $\Leftrightarrow$  left/on7 line/right. If the optional argument eps is given 0 is returned if p is within distance eps from the line. P is supposed to be Point<T> where T is e.g.8 double or long long. It uses products in intermediate steps so watch out for9 overflow if using int or long long.

**Usage:** bool left = sideOf(p1,p2,q)==1;

"Point.h" 3af81c, 9 line22

```
1 template <class P>
2 int sideOf(P s, P e, P p) { return sgn(s.cross(e, p)); }
3
4 template <class P>
5 int sideOf(const P& s, const P& e, const P& p, double eps) {
6     auto a = (e-s).cross(p-s);
7     double l = (e-s).dist()*eps;
8     return (a > l) - (a < -l);
9 }
```

#### OnSegment.h

**Description:** Returns true iff p lies on the line segment from s to e. Use (segDist(s,e,p)<=epsilon) instead when using Point<double>.

"Point.h" c597e8, 3 lines

```
1 template <class P> bool onSegment(P s, P e, P p) {
2     return p.cross(s, e) == 0 && (s - p).dot(e - p) <= 0;
```

```
3 }
```

#### linearTransformation.h

##### Description:

Apply the linear transformation (translation, rotation and scaling) which takes line p0-p1 to line q0-q1 to point r.

"Point.h" 03a306, 6 lines

```
1 typedef Point<double> P;
2 P linearTransformation(const P& p0, const P& p1,
3     const P& q0, const P& q1, const P& r) {
4     P dp = p1-p0, dq = q1-q0, num(dp.cross(dq), dp.dot(dq));
5     return q0 + P((r-p0).cross(num), (r-p0).dot(num))/dp.dist2
6     ();
```

#### LineProjRefl.h

**Description:** Projects point p onto line ab. Set refl=true to get reflection of point p across line ab insted. The wrong point will be returned if P is an integer point and the desired point doesn't have integer coordinates. Products of three coordinates are used in intermediate steps so watch out for overflow.

"Point.h" b5562d, 5 lines

```
1 template <class P>
2 P lineProj(P a, P b, P p, bool refl=false) {
3     P v = b - a;
4     return p - v.perp()*(1+refl)*v.cross(p-a)/v.dist2();
5 }
```

#### Angle.h

**Description:** A class for ordering angles (as represented by int points and a number of rotations around the origin). Useful for rotational sweeping. Sometimes also represents points or vectors.

**Usage:** vector<Angle> v = {w[0].t360() ...}; // sorted  
int j = 0; rep(i,0,n) { while (v[j] < v[i].t180()) ++j; }  
// sweeps j such that {j-i} represents the number of positively oriented triangles with vertices at 0 and i

0f0602, 31 lines

```
1 struct Angle {
2     int x, y;
3     int t;
4     Angle(int x, int y, int t=0) : x(x), y(y), t(t) {}
5     Angle operator-(Angle b) const { return {x-b.x, y-b.y, t}; }
6     int half() const { assert(x || y); return y < 0 || (y == 0
7         && x < 0); }
8     Angle t90() const { return {-y, x, t + (half() && x >= 0)
9         }; }
10    Angle t180() const { return {-x, -y, t + half()}; }
11    Angle t360() const { return {x, y, t + 1}; }
12 };
13 bool operator<(Angle a, Angle b) {
14     // add a.dist2() and b.dist2() to also compare distances
15     return make_tuple(a.t, a.half(), a.y * (1l)b.x) <
16     make_tuple(b.t, b.half(), a.x * (1l)b.y);
17 }
```

// Given two points, this calculates the smallest angle between them, i.e., the angle that covers the defined line segment.

pair<Angle, Angle> segmentAngles(Angle a, Angle b) {  
 if (b < a) swap(a, b);  
 return (b < a.t180() ?  
 make\_pair(a, b) : make\_pair(b, a.t360()));  
}

Angle operator+(Angle a, Angle b) { // point a + vector b  
 Angle r(a.x + b.x, a.y + b.y, a.t);  
 if (a.t180() < r) r.t--;  
 return r.t180() < a ? r.t360() : r;

```
27 }
28 Angle angleDiff(Angle a, Angle b) { // angle b - angle a
29     int tu = b.t - a.t; a.t = b.t;
30     return {a.x*b.x + a.y*b.y, a.x*b.y - a.y*b.x, tu - (b < a)
31     };
```

### 8.2 Circles

#### CircleIntersection.h

**Description:** Computes the pair of points at which two circles intersect. Returns false in case of no intersection.

"Point.h" 84d6d3, 10 lines

```
1 typedef Point<double> P;
2 bool circleInter(P a,P b,double r1,double r2,pair<P, P>* out
    ) {
3     if (a == b) { assert(r1 != r2); return false; }
4     P vec = b - a;
5     double d2 = vec.dist2(), sum = r1+r2, dif = r1-r2,
6         p = (d2 + r1*r1 - r2*r2)/(d2*2), h2 = r1*r1 - p*p*d
7         2;
8     if (sum*sum < d2 || dif*dif > d2) return false;
9     P mid = a + vec*p, per = vec.perp() * sqrt(fmax(0, h2) / d
10        2);
11     *out = {mid + per, mid - per};
12     return true; }
```

### CircleTangents.h

**Description:** Finds the external tangents of two circles, or internal if r2 is negated. Can return 0, 1, or 2 tangents – 0 if one circle contains the other (or overlaps it, in the internal case, or if the circles are the same); 1 if the circles are tangent to each other (in which case .first = .second and the tangent line is perpendicular to the line between the centers). .first and .second give the tangency points at circle 1 and 2 respectively. To find the tangents of a circle 1 with a point set r2 to 0.

```
1 template<class P>
2 vector<pair<P, P>> tangents(P c1, double r1, P c2, double r2
    ) {
3     P d = c2 - c1;
4     double dr = r1 - r2, d2 = d.dist2(), h2 = d2 - dr * dr;
5     if (d2 == 0 || h2 < 0) return {};
6     vector<pair<P, P>> out;
7     for (double sign : {-1, 1}) {
8         P v = (d * dr + d.perp() * sqrt(h2) * sign) / d2;
9         out.push_back({c1 + v * r1, c2 + v * r2});
10    }
11    if (h2 == 0) out.pop_back();
12    return out; }
```

### CircleLine.h

**Description:** Finds the intersection between a circle and a line. Returns a vector of either 0, 1, or 2 intersection points. P is intended to be Point<double>.

```
1 template<class P> vector<P> circleLine(P c, double r, P a, P
    b) {
2     P ab = b - a, p = a + ab * (c-a).dot(ab) / ab.dist2();
3     double s = a.cross(b, c), h2 = r*r - s*s / ab.dist2();
4     if (h2 < 0) return {};
5     if (h2 == 0) return {p};
6     P h = ab.unit() * sqrt(h2);
7     return {p - h, p + h}; }
```

### CirclePolyIntersection.h

**Description:** Returns the area of the intersection of a circle with a ccw polygon.

```
1 typedef Point<double> P;
2 #define arg(p, q) atan2(p.cross(q), p.dot(q))
3 double circlePoly(P c, double r, vector<P> ps) {
4     auto tri = [&](P p, P q) {
5         auto r2 = r * r / 2;
6         P d = q - p;
7         auto a = d.dot(p)/d.dist2(), b = (p.dist2()-r*r)/d.dist2
8             ();
9         auto det = a * a - b;
10        if (det <= 0) return arg(p, q) * r2;
11        auto s = max(0., -a+sqrt(det)), t = min(1., -a+sqrt(det)
12            );
13        if (t < 0 || 1 <= s) return arg(p, q) * r2;
14        P u = p + d * s, v = p + d * t;
15        return arg(p,u) * r2 + u.cross(v)/2 + arg(v,q) * r2;
16    };
17    auto sum = 0.0;
18    rep(i,0,sz(ps))
19        sum += tri(ps[i] - c, ps[(i + 1) % sz(ps)] - c);
20    return sum; }
```

### circumcircle.h

**Description:**

```
1 ccRadius = radius and ccCenter = center of circle through
2 points A, B, C.
3
4 "Point.h" 1caa3a, 7 lines
5
6 typedef Point<double> P;
7 double ccRadius(const P& A, const P& B, const P& C) {
8     return (B-A).dist()* (C-B).dist()* (A-C).dist() /
9         abs((B-A).cross(C-A))/2; }
10 P ccCenter(const P& A, const P& B, const P& C) {
11     P b = C-A, c = B-A;
12     return A + (b*c.dist2()-c*b.dist2()).perp()/b.cross(c)/2;
13 }
```

### MinimumEnclosingCircle.h

**Description:** Computes the minimum circle that encloses a set of points.

```
1 Time: expected O(n)
2 "circumcircle.h" 09dd0a, 17 lines
3 pair<P, double> mec(vector<P> ps) {
4     shuffle(all(ps), mt19937(time(0)));
5     P o = ps[0];
6     double r = 0, EPS = 1 + 1e-8;
7     rep(i,0,sz(ps)) if ((o - ps[i]).dist() > r * EPS) {
8         o = ps[i], r = 0;
9         rep(j,0,i) if ((o - ps[j]).dist() > r * EPS) {
10            o = (ps[i] + ps[j]) / 2;
11            r = (o - ps[i]).dist();
12            rep(k,0,j) if ((o - ps[k]).dist() > r * EPS) {
13                o = ccCenter(ps[i], ps[j], ps[k]);
14                r = (o - ps[i]).dist();
15            }
16        }
17    }
18    return {o, r};
19 }
```

## 8.3 Polygons

### InsidePolygon.h

**Description:** Returns true if p lies within the polygon. If strict is true, it returns false for points on the boundary. The algorithm uses products in intermediate steps so watch out for overflow.

```
1 Usage: vector<P> v = {P{4,4}, P{1,2}, P{2,1}};
2 bool in = inPolygon(v, P{3, 3}, false);
3 Time: O(n)
4 "Point.h", "OnSegment.h", "SegmentDistance.h" 2bf504, 11 lines
5
6 template<class P>
7 bool inPolygon(vector<P> &p, P a, bool strict = true) {
8     int cnt = 0, n = sz(p);
9     rep(i,0,n) {
10        P q = p[(i + 1) % n];
11        if (onSegment(p[i], q, a)) return !strict;
12        //or: if (segDist(p[i], q, a) <= eps) return !strict;
13        cnt ^= ((a.y<p[i].y) - (a.y<q.y)) * a.cross(p[i], q) > 0
14            ;
15    }
16    return cnt;
17 }
```

### PolygonArea.h

**Description:** Returns twice the signed area of a polygon. Clockwise enumeration gives negative area. Watch out for overflow if using int as T!

```
1 "Point.h" f12300, 6 lines
2
3 template<class T>
4 T polygonArea2(vector<Point<T>>& v) {
5     T a = v.back().cross(v[0]);
6     rep(i,0,sz(v)-1) a += v[i].cross(v[i+1]);
7     return a;
8 }
```

### PolygonCenter.h

**Description:** Returns the center of mass for a polygon.

```
1 Time: O(n)
2 "Point.h" 9706dc, 9 lines
3
4 typedef Point<double> P;
5 P polygonCenter(const vector<P>& v) {
6     P res(0, 0); double A = 0;
7 }
```

```
1 for (int i = 0, j = sz(v) - 1; i < sz(v); j = i++) {
2     res = res + (v[i] + v[j]) * v[j].cross(v[i]);
3     A += v[j].cross(v[i]);
4 }
5 return res / A / 3;
6 }
```

### PolygonCut.h

**Description:**

Returns a vector with the vertices of a polygon with everything to the left of the line going from s to e cut away.

```
1 Usage: vector<P> p = ...;
2 p = polygonCut(p, P(0,0), P(1,0));
3 "Point.h", "LineIntersection.h" f2b7d4, 13 lines
4
5 typedef Point<double> P;
6 vector<P> polygonCut(const vector<P>& poly, P s, P e) {
7     vector<P> res;
8     rep(i,0,sz(poly)) {
9         P cur = poly[i], prev = i ? poly[i-1] : poly.back();
10        bool side = s.cross(e, cur) < 0;
11        if (side != (s.cross(e, prev) < 0))
12            res.push_back(lineInter(s, e, cur, prev).second);
13        if (side) res.push_back(cur);
14    }
15    return res;
16 }
```

### PolygonUnion.h

**Description:** Calculates the area of the union of n polygons (not necessarily convex). The points within each polygon must be given in CCW order. (Epsilon checks may optionally be added to sideOf/sgn, but shouldn't be needed.)

**Time:**  $O(N^2)$ , where N is the total number of points

```
1 "Point.h", "sideOf.h" 3931c6, 33 lines
2
3 typedef Point<double> P;
4 double rat(P a, P b) { return sgn(b.x) ? a.x/b.x : a.y/b.y;
5 }

11        (sideOf(l[0], l[c], p) > 0 ? b : a) = c;
12    }
13    return sgn(l[a].cross(l[b], p)) < r;
14 }

```

## LineHullIntersection.h

**Description:** Line-convex polygon intersection. The polygon must be ccw and have no collinear points. lineHull(line, poly) returns a pair describing the intersection of a line with the polygon:  $\bullet(-1, -1)$  if no collision,  $\bullet(i, -1)$  if touching the corner  $i$ ,  $\bullet(i, i)$  if along side  $(i, i+1)$ ,  $\bullet(i, j)$  if crossing sides  $(i, i+1)$  and  $(j, j+1)$ . In the last case, if a corner  $i$  is crossed, this is treated as happening on side  $(i, i+1)$ . The points are returned in the same order as the line hits the polygon. extrVertex returns the point of a hull with the max projection onto a line.

**Time:**  $\mathcal{O}(\log n)$

## HalfPlaneIntersection.h

**Description:** Returns vertices of half-plane intersection. A half-plane is the area to the left of a ray, which is defined by a point p and a direction dp. Area of intersection should be sufficiently precise when all inputs are integers with magnitude  $\leq 10^6$ . Intersection must be bounded. Probably works with floating point too (but EPS might need to be adjusted?).

**Time:**  $\mathcal{O}(N \log N)$

```

```

### sphericalDistance.h

Description: Returns the shortest distance on the sphere with radius radius between the points with azimuthal angles (longitude)  $f_1$  ( $\phi_1$ ) and  $f_2$  ( $\phi_2$ ) from x axis and zenith angles (latitude)  $t_1$  ( $\theta_1$ ) and  $t_2$  ( $\theta_2$ ) from z axis (0 = north pole). All angles measured in radians. The algorithm starts by converting the spherical coordinates to cartesian coordinates so if that is what you have you can use only the two last rows.  $dx*$ radius is then the difference between the two points in the x direction and  $d*$ radius is the total distance between the points.

611f07, 8 lines

```

1 double sphericalDistance(double f1, double t1,
2     double f2, double t2, double radius) {
3     double dx = sin(t2)*cos(f2) - sin(t1)*cos(f1);
4     double dy = sin(t2)*sin(f2) - sin(t1)*sin(f1);
5     double dz = cos(t2) - cos(t1);
6     double d = sqrt(dx*dx + dy*dy + dz*dz);
7     return radius*2*asin(d/2);
8 }

```

## Strings (9)

### KMP.h

Description:  $pi[x]$  computes the length of the longest prefix of  $s$  that ends at  $x$ , other than  $s[0..x]$  itself (abacaba -> 0010123). Can be used to find all occurrences of a string.

13 }
14 for (a = t; v[a+m-t] < 0; a--);
15 return a;
16 }
```

### 10.3 Dynamic programming

**KnuthDP.h**  
**Description:** When doing DP on intervals:  $a[i][j] = \min_{i < k < j} (a[i][k] + a[k][j]) + f(i, j)$ , where the (minimal) optimal  $k$  increases with both  $i$  and  $j$ , one can solve intervals in increasing order of length, and search  $k = p[i][j]$  for  $a[i][j]$  only between  $p[i][j - 1]$  and  $p[i + 1][j]$ . This is known as Knuth DP. Sufficient criteria for this are if  $f(b, c) \leq f(a, d)$  and  $f(a, c) + f(b, d) \leq f(a, d) + f(b, c)$  for all  $a \leq b \leq c \leq d$ . Consider also: LineContainer (ch. Data structures), monotone queues, ternary search.  
**Time:**  $O(N^2)$

**DivideAndConquerDP.h**  
**Description:** Given  $a[i] = \min_{l \leq i \leq k} (f(i, k))$  where the (minimal) optimal  $k$  increases with  $i$ , computes  $a[i]$  for  $i = L..R - 1$ .  
**Time:**  $O((N + (hi - lo)) \log N)$

```
1 struct DP { // Modify at will:
2     int lo(int ind) { return 0; }
3     int hi(int ind) { return ind; }
4     ll f(int ind, int k) { return dp[ind][k]; }
5     void store(int ind, int k, ll v) { res[ind] = pii(k, v); }
6
7     void rec(int L, int R, int LO, int HI) {
8         if (L >= R) return;
9         int mid = (L + R) >> 1;
10        pair<ll, int> best (LLONG_MAX, LO);
11        rep(k, max(LO, lo(mid)), min(HI, hi(mid)))
12            best = min(best, make_pair(f(mid, k), k));
13        store(mid, best.second, best.first);
14        rec(L, mid, LO, best.second+1);
15        rec(mid+1, R, best.second, HI);
16    }
17    void solve(int L, int R) { rec(L, R, INT_MIN, INT_MAX); }
18 };
```

### 10.4 Debugging tricks

- `signal(SIGSEGV, [](int) { _Exit(0); });` converts segfaults into Wrong Answers. Similarly one can catch SIGABRT (assertion failures) and SIGFPE (zero divisions). `_GLIBCXX_DEBUG` failures generate SIGABRT (or SIGSEGV on gcc 5.4.0 apparently).
- `feenableexcept(29);` kills the program on NaNs (1), 0-divs (4), infinities (8) and denormals (16).

### 10.5 Optimization tricks

`__builtin_ia32_ldmxcsr(40896);` disables denormals (which make floats 20x slower near their minimum value).

#### 10.5.1 Bit hacks

- `x & -x` is the least bit in `x`.
- `for (int x = m; x; ) { --x &= m; ... }` loops over all subset masks of `m` (except `m` itself).
- `c = x&-x, r = x+c; ((r^x) >> 2)/c | r` is the next number after `x` with the same number of bits set.
- `rep(b,0,K) rep(i,0,(1 << K))`  
    if (`i & 1 << b`) `D[i] += D[i^(1 << b)]`;  
    computes all sums of subsets.

#### 10.5.2 Pragmas

- **#pragma** GCC optimize ("Ofast") will make GCC auto-vectorize loops and optimizes floating points better.
- **#pragma** GCC target ("avx2") can double performance of vectorized code, but causes crashes on old machines.
- **#pragma** GCC optimize ("trapv") kills the program on integer overflows (but is really slow).

**FastMod.h**  
**Description:** Compute  $a \% b$  about 5 times faster than usual, where  $b$  is constant but not known at compile time. Returns a value congruent to  $a \pmod b$  in the range  $[0, 2b)$ .  
751a02, 8 lines

```
1 typedef unsigned long long ull;
2 struct FastMod {
3     ull b, m;
4     FastMod(ull b) : b(b), m((-1ULL / b) {}) {
5         ull reduce(ull a) { // a % b + (0 or b)
6             return a - (ull)((__uint128_t(m) * a) >> 64) * b;
7         }
8     };
9 }
```

**FastInput.h**  
**Description:** Read an integer from stdin. Usage requires your program to pipe in input from file.  
**Usage:** `./a.out < input.txt`  
**Time:** About 5x as fast as `cin/scanf`.

```
1 inline char gc() { // like getchar()
2     static char buf[1 << 16];
3     static size_t bc, be;
4     if (bc >= be) {
5         buf[0] = 0, bc = 0;
6         be = fread(buf, 1, sizeof(buf), stdin);
7     }
8     return buf[bc++]; // returns 0 on EOF
9 }
10
11 int readInt() {
12     int a, c;
13     while ((a = gc()) < 40);
14     if (a == '-') return -readInt();
15     while ((c = gc()) >= 48) a = a * 10 + c - 48;
16     return a - 48;
17 }
```

**BumpAllocator.h**  
**Description:** When you need to dynamically allocate many objects and don't care about freeing them. "new X" otherwise has an overhead of something like 0.05us + 16 bytes per allocation.  
745db2, 8 lines

```
1 // Either globally or in a single class:
2 static char buf[450 << 20];
3 void* operator new(size_t s) {
4     static size_t i = sizeof buf;
5     assert(s < i);
6     return (void*)&buf[i -= s];
7 }
8 void operator delete(void*) {}
```

**SmallPtr.h**  
**Description:** A 32-bit pointer that points into BumpAllocator memory.  
2dd6c9, 10 lines

```
1 template<class T> struct ptr {
